COMPLETE SPECIFICATION

DRAWINGS ATTACHED

Improvements in or relating to Flexible Barges or Storage Vessels

WE, DRACONE DEVELOPMENTS LIMITED, a British Company, of 7 Tilney Street, London, W.1., do hereby declare the invention, for which we pray that a patent may 5 be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:

This invention relates to flexible barges or storage vessels for transporting or storing 10 liquid or solid cargoes in or on inland waters

or the sea.

It is desirable that the walls of such barges or storage vessels be such that they can be collapsed or folded. It is desirable, there-15 fore, that the material of such walls be a fabric-like material which can be rolled up, crushed or folded,, and which has a good tensile strength, withstands shear and flexing, is impervious to the cargo, is unattacked 20 by water or organisms and withstands weather and sun, abrasion, ripping or puncturing.

According to the invention, a barge or storage vessel of the kind indicated is formed 25 with unsupported walls made up of several load bearing layers of woven or oriented natural or synthetic fibres such as Rayon, Nylon, Terylene (Registered Trade Mark), glass fibres or wire, the composite walls be-30) ing provided with inner and outer skins of material capable of protecting the load-bearing layers from attack by the intended cargo or by the atmosphere, as the case may be, without necessarily contributing material-35 ly to the load-bearing properties of the

composite walls.

Tightly woven multi-ply fabrics may be used and may not need extra layers of biased fabric to resist shear. Where orienta-40 tion is used without weaving, the fibres or filaments or adjacent layers are preferably arranged at an angle to each other. Glass fibre may be used where continued flexing is not likely to occur, for example in storage tanks. Natural fibres may be used where 45 low-strength fabrics are permissible or where extra thickness is required without appreci-

able additional strength.

The various layers may be made separately, for example, by weaving in one tubular or 50 other shaped piece, and then inserted one inside the other. Internal pressure may be used to hold one layer against the other, or the layers may be held together at appropriately distributed areas or bands by 55 sewing or rivetting or by bonding with glue, plastic or natural or synthetic rubber. Alternatively, the layers may be bonded together throughout.

The inner skin may be of rubber-like 60 material chosen so that it is not attacked by the contents of the barge. The composite walls may be of woven nylon fabric which carries the skin stresses, consisting of lengths of nylon cloth overlapped at the 65 edges and these stuck and sewn together to form one shaped tube. The outer skin may be of rubber-like material similar to the inner layer but chosen so that it resists attack from external agencies such as sea water and 7() The protecting skins and loadsunlight. bearing fabric may be made separately and then bonded together but the two skins may be bonded to the nylon cloth before it is made up into the shape of the barge, and 75 then in their turn stuck together to form the barge or storage vessel.

Where the layers are not bonded together throughout, they may be lubricated by means of a liquid, such as water, or by means 80 of graphite, carbon black or other lubricant, to protect the yarns and remove heat generated during flexing. Where water is used as a lubricant, this may be derived from the outside water by giving this access to the 85

interior of the fabric of the vessel.

Where the filaments or fibres of one layer are arranged at an angle to those of adjacent layers, oppositely handed helical windings may be disposed one within the other.

Where a woven fabric is employed the relative strengths of the warp and weft are preferably chosen to suit the requirements of the vessel. The material may be arranged so that its greatest strength is developed in 10 the circumferential or hoop direction. This would normally mean that the warp yarns would run circumferentially and the weft yarns longitudinally of the axis of the barge or storage vessel and joints would 15 preferably be circumferential, longitudinal joints being kept to a minimum. However, longitudinally joined strips may be used as hereinafter described.

In a barge of, for example 30' in diameter 20 and 600' in length, the ultimate strength of the fabric is preferably not less than 6,000 lb. per inch width of fabric in the circumferential direction and not less than 3,500 lbs. per inch in the longitudinal direction.

25 For different diameters the required strength could be allowed to vary as the square of the diameter.

Each yarn may be covered with a layer of rubber or plastic to bind the cloth and 30 to reduce fretting between the layers, and each layer of cloth may be covered with a binder or with a plastic protective coating. For oil-carrying vessels, natural rubber may be used between the layers so that in the 35 event of leakage some self-sealing action is

Some seepage of fluid cargo is likely where the fabric is under tension. To reduce such seepage, the inner skin may be made more 40 extensible than the load-bearing layer or layers and it may be fitted slightly oversize. Sufficient extensibility may be obtained by using "two-way stretch" or "crepe" Nylon, rubberised throughout or on one side only.

For some cargoes more than one sealing skin may be used and the skin may be sealed with plastic or rubber. Skins may be separated by fabric in a multi-layer construction.

Impregnating and colouring materials may 50 be used on the outer skin to reduce the effects of biological attack, sunlight and weathering.

For oil-carrying barges, the inner skin may be rubberised with an oil-resistant material 55 such as Hycar (Registered Trade Mark) (a butadiene based artificial rubber) which has been found to adhere satisfactorily to Nylon. The external skin may be of Hycar rubber, neoprene or a plastic such as polyvinyl

For example, in a preferred embodiment of this invention the stress carrying fabric consists of lengths of multi-layer Nylon cloth, with a strength of 1,000 lbs. per inch 65 width of fabric in both directions.

lengths are shaped and overlapped longitudinally where they are joined by both sticking and sewing. The glue for sticking the overlap is applied immediately below the sewing so that the material and the stiches are all 70 glued together. The nylon cloth is coated on the inside with Hycar rubber bonded to the material and on the outside with neoprene bonded similarly.

Embodiments of the invention will now be 75 described by way of example with reference to the drawings accompanying the Provis-

ional Specification, in which:

Fig. 1 is a fragmentary diagrammatic sectional view of one example of multi-layer 80 fabric for constructing a barge according to the invention, and

Figs. 2-6 show similar views of examples

of joints in the fabric.

Reference will also be made to the draw- 85 ings accompanying the present specification, in which :-

Fig. 1 is a fragmentary view of a portion of said fabric for constructing a barge according to the invention;

Fig. 2 is a diagrammatic view of two such portions joined together, the joint being shown partially opened;

Fig. 3 is a fragmentary side sectional elevation of one end of a barge formed from 95 portions of material according to Fig. 1 Fig. 4 is a section on the line IV-IV of Fig. 3; and

Fig. 5 is an enlarged view of a joint such

as is illustrated in Figs. 2 and 4.

Referring first to Fig. 1 of the drawings accompanying the Provisional Specification. this shows an example of multi-layer fabric for use in constructing a barge according to the invention, said fabric consisting of six 105 layers of nylon cloth 1-6, furnished with an external fabric 7 of neoprene and nylon and an internal sealing fabric 8 of Hycar and nylon.

One of the requirements is that the 110 material should stand up to kinking. To avoid the failure of the proofing under kinking, the proofing should be kept as thin as possible. This makes desirable the use of one or more layers of thinly proofed material. 115.

Fig. 2 shows a lap joint of the material illustrated in Fig. 1, the material being spliced as indicated by the line 9 and sewn as indicated by the broken lines 10, or the material may be stuck instead of, or in 120 addition to. sewing, and the lap joint thus formed sealed with plastic or rubber 11, 12.

Fig. 3 shows a joint in similar fabric, except that only five layers of nylon are shown and instead of splicing the material in Fig. 125 4a and the outer rubber or plastic seals consist of rubberised or plasticised reinforcing strips 13, 14 respectively of which the rubberizing or plasticising is shown at 13a and 14a respectively. The whole may then 130
